1. The Northcott property.

The Northcott property

Let $\alpha \in \overline{\mathbb{Q}}$. We define its height by

$$h(\alpha) = \frac{1}{[k : \mathbb{Q}]} \sum_{v \in M_k} d_v \log \max\{1, |\alpha|_v\},$$

where M_k is the set of places v of a number field k containing α , and d_v the local degree.

The height h satisfies the *Northcott property*: for any fixed real numbers D, H , the set

$$\left\{ \alpha \in \overline{\mathbb{Q}} \mid \deg(\alpha) \leq D, \quad h(\alpha) \leq H \right\}$$

is finite.

More generally, we talk about the Northcott property for general functions with values in an ordered set.

More generally, we talk about the Northcott property for general functions with values in an ordered set.

Here is an example: a theorem of Hermite ensures that the set of number fields k with bounded discriminant Δ_k is finite. So the function $k \rightarrow |\Delta_k|$ satisfies a Northcott property.

More generally, we talk about the Northcott property for general functions with values in an ordered set.

Here is an example: a theorem of Hermite ensures that the set of number fields k with bounded discriminant Δ_k is finite. So the function $k \rightarrow |\Delta_k|$ satisfies a Northcott property.

Now a different question: pick a curve C of genus $g \geq 2$, defined over a number field k . How does one prove that $C(k)$ is finite?

Definition: the Faltings height of an abelian variety A/k is the Arakelov degree of the line bundle $\omega_{A/S}$, for the metric given by $||s||_v^2 = \frac{1}{2g} \int_{A(\bar{k}_v)} |s \wedge \bar{s}| :$

$$h_{\text{Falt}}(A/k) = \frac{1}{[k : \mathbb{Q}]} \deg_{\text{Ar}}(\omega_{A/S})$$

Definition: the Faltings height of an abelian variety A/k is the Arakelov degree of the line bundle $\omega_{A/S}$, for the metric given by $||s||_v^2 = \frac{1}{2g} \int_{A(\bar{k}_v)} |s \wedge \bar{s}| :$

$$h_{\text{Falt}}(A/k) = \frac{1}{[k : \mathbb{Q}]} \deg_{\text{Ar}}(\omega_{A/S})$$

Remark: it doesn't depend on any projective model.

Definition: the Faltings height of an abelian variety A/k is the Arakelov degree of the line bundle $\omega_{A/S}$, for the metric given by $\|s\|_v^2 = \frac{1}{2g} \int_{A(\bar{k}_v)} |s \wedge \bar{s}|$:

$$h_{\text{Falt}}(A/k) = \frac{1}{[k : \mathbb{Q}]} \deg_{\text{Ar}}(\omega_{A/S})$$

Remark: it doesn't depend on any projective model.

For elliptic curves, we have

$$h_{\text{Falt}}(E/k) \gg \ll \max\{\log |N_{k/\mathbb{Q}}(\Delta_{E/k})|, h(j_E)\}.$$

Definition: the Faltings height of an abelian variety A/k is the Arakelov degree of the line bundle $\omega_{A/S}$, for the metric given by $\|s\|_v^2 = \frac{1}{2g} \int_{A(\bar{k}_v)} |s \wedge \bar{s}|$:

$$h_{\text{Falt}}(A/k) = \frac{1}{[k : \mathbb{Q}]} \deg_{\text{Ar}}(\omega_{A/S})$$

Remark: it doesn't depend on any projective model.

For elliptic curves, we have

$$h_{\text{Falt}}(E/k) \gg \ll \max\{\log |N_{k/\mathbb{Q}}(\Delta_{E/k})|, h(j_E)\}.$$

Fact: the Faltings height satisfies a Northcott property. This plays a crucial role in the proof of the Mordell Conjecture.

Comparing heights

Strategy: To prove that h_{Falt} satisfies a Northcott property, the strategy is to *compare* h_{Falt} with another height function (say the theta height, or any reasonable height on the moduli space of principally polarized abelian varieties) and deduce the Northcott property from this other height function.

Typically we get

The Northcott property for Kato's height is not known yet. Special instances by Koshikawa (2015, 2016) and by Nguyen (2020) are proved.

Strategy: Inspired by the proof of the Northcott property for the Faltings height, we try to *compare* its generalization, the Kato height, to other interesting quantities. We do not have a theta height for motives, so we need to be creative!

The Northcott property for Kato's height is not known yet. Special instances by Koshikawa (2015, 2016) and by Nguyen (2020) are proved.

Strategy: Inspired by the proof of the Northcott property for the Faltings height, we try to *compare* its generalization, the Kato height, to other interesting quantities. We do not have a theta height for motives, so we need to be creative!

Question: what kind of height function could help us measure the complexity of a motive?

Height functions: what about L-functions?

We would like to investigate what can be said of the following function: for a mixed motive $X \in \mathcal{MM}(F; \mathbb{Q})$ defined over a number field F , the special value

$$h_n(X) := |L^*(X, n)|,$$

where n is a natural integer and, whenever the limit exists,

$$L^*(X, n) := \lim_{s \rightarrow n} \frac{L(X, s)}{(s - n)^{\text{ord}_{s=n}(L(X, s))}}.$$

4. Heights of motives: two first results.

Northcott property for $\zeta_K(0)$ but not for $\zeta_K(1)$

Theorem (P.-Pengo, 2024)

Let S be the set of isomorphism classes of number fields. Let ζ_F stand for the Dedekind zeta function of the field F .

(z1) The sets $\{[F] \in S : |\zeta_F^(1)| \leq B\}$ are infinite, for every big enough $B \in \mathbb{R}_{>0}$.*

(z0) For every $B \in \mathbb{R}_{>0}$ the set $S_B := \{[F] \in S : |\zeta_F^(0)| \leq B\}$ is finite. Moreover, there exist two absolute, effectively computable constants $c_1, c_2 \in \mathbb{R}_{>0}$ such that:*

$$|S_B| \leq \exp \left(c_1 B^{c_2 \log \log(B)} (\log \log(B))^3 \right)$$

for every $B \in \mathbb{R}_{>3}$, where $|S_B|$ stands for the cardinal of S_B .

A part of the proof relies on the analytic class number formula:

$$\zeta_F^*(0) = -\frac{h_F}{w_F} R_F \quad \zeta_F^*(1) = \frac{2^{r_1} (2\pi)^{r_2} h_F}{w_F |D_F|^{1/2}} R_F$$

where h_F, R_F, w_F, D_F are respectively the class number, the regulator, the number of roots of unity of F and the discriminant of F .

For (z1), we may restrict our attention to F being an imaginary quadratic field, which implies that R_F is trivial. A result of Barban states that there exist $c_1, c_2 \in \mathbb{R}_{>0}$ such that:

$$\frac{1}{X} \sum_{\substack{D \in \mathcal{D} \\ |D| \leq X}} h_{\mathbb{Q}(\sqrt{-D})} = c_1 \sqrt{X} (1 + O(e^{-c_2 \sqrt{\log(X)}}))$$

when $X \rightarrow +\infty$

Theorem (P.-Pengo, 2024)

Let F a number field. Fix an integer $w \in \mathbb{Z}$. Let S be the set of isomorphism classes of pure motives in $\mathcal{MM}(F; \mathbb{Q})$. Then for every $B_1, B_2 \in \mathbb{R}_{\geq 0}$ and every $n \in \mathbb{Z}$ such that $n < w/2$, the set

$$\{[X] \in S, |L^*(X, n)| \leq B_1, \dim(X) \leq B_2\}$$

is finite, under the assumption that the motivic L-functions $L(X, s)$ are well defined, can be meromorphically continued to the whole complex plane, and satisfy a functional equation.

What about the center of the critical strip?

In other words, the height $h_n: S \rightarrow \mathbb{R}_{\geq 0}$ defined as $h_n(X) := |L^*(X, n)|$ has the Northcott property, when restricted to the subset of isomorphism classes of pure motives of weight $w > 2n$, under reasonable assumptions.

Note: The two theorems are enough to give a complete unconditional answer for $\zeta_F^*(n)$ for any fixed $n \in \mathbb{Z}$.

Question: However, it would also be interesting to understand the behaviour of the special values at the center: can one say something about the values at $s = 1/2$?

5. Values at $1/2$.

Away from integers

For the Dedekind zeta function, we obtain a result valid for any real $\sigma \geq 1/2$.

Theorem (Caro-P.-Pengo, 2025)

Let S be the set of isomorphism classes of number fields. Let us consider the function $h_\sigma: S \rightarrow \mathbb{R}_{\geq 0}$ defined by

$$h_\sigma([K]) := |\zeta_K^*(\sigma)|.$$

For every $\sigma \in [\frac{1}{2}, +\infty)$ and every $B \in (\inf(h_\sigma(S)), +\infty)$ the intersection $h_\sigma(S) \cap (0, B)$ is infinite.

In other words, the height h_σ does not have the Northcott property, when $\sigma \geq 1/2$.

Elements of proof

- ▶ On the critical line, *i.e.* when $\sigma = \frac{1}{2}$, we study the second moment of the resonator coefficients constructed by Soundararajan for L -functions attached to quadratic characters.
- ▶ Inside the critical strip, but not on the critical line, *i.e.* when $\sigma \in (\frac{1}{2}, 1)$, we employ previous work of Lamzouri, concerning the similarities between the distribution of values of quadratic Dirichlet L -functions and random Euler products.
- ▶ On the boundary of the critical strip, *i.e.* when $\sigma = 1$, we use previous work of Granville and Soundararajan, which proves that special values of quadratic L -functions at $\sigma = 1$ are distributed like random Euler products.
- ▶ In the region of absolute convergence, *i.e.* when $\sigma \in (1, +\infty)$, we construct explicit families of number fields $\{K_d\}_{d \in \mathbb{N}}$ such that $[K_d : \mathbb{Q}] \rightarrow +\infty$ and $\zeta_{K_d}(\sigma) \rightarrow 1$ as $d \rightarrow +\infty$. We do so by imposing that many rational primes stay inert in each field K_d .

Northcott
property for
special values of
 L -functions at
integers and at
 $1/2$

- (A) The conjectures of Boyd, which relate certain special values of L -functions to the Mahler measure of integral polynomials. The first examples are due to Smyth:

$$m(x + y + 1) = \frac{3\sqrt{3}}{4\pi} L(\chi_{-3}, 2),$$

and

$$m(x + y + z + 1) = \frac{7}{2\pi^2} \zeta(3).$$

- (B) The formula of Gross and Zagier (1986), relating special values of L -functions of modular forms to heights of Heegner points, with the following important consequence: let E be an elliptic curve, let ω be a Néron differential, c be the Manin constant, let $K = \mathbb{Q}(\sqrt{-D})$ be such that P_K is a Heegner point on E , and \mathcal{O}_K^* the units in K , then

$$L'(E/K, 1) = \frac{\|\omega\|^2}{c^2 |(\mathcal{O}_K^*)_{tors}|^2 \sqrt{D}} \hat{h}_E(P_K).$$

- (C) The conjecture of Colmez, which relates logarithmic derivatives of Artin L -functions to the Faltings height of a CM abelian variety A :

$$h_{\text{Falt}}(A) \stackrel{?}{=} \sum_{\chi} m_{(E, \Phi)}(\chi) \left(\frac{L'(\chi, 0)}{L(\chi, 0)} + \log(f_{\chi}) \right),$$

where (E, Φ) is the CM-type of A and the sum runs over all the Artin characters $\chi: \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \rightarrow \mathbb{C}$ of conductor f_{χ} whose value on complex conjugation $c \in \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$ equals $\chi(c) = -1$.

(The numbers $m_{(E, \Phi)}(\chi)$ are rational and almost all of them are zero, the traditional minus sign is included...)

(D) The strong form of the Birch and Swinnerton-Dyer conjecture, given here for an abelian variety (by Tate) over \mathbb{Q} :

$$L^*(A, 1) \stackrel{?}{=} \frac{\Omega_\infty \prod c_p \# \text{III}(A, \mathbb{Q})}{\# A(\mathbb{Q})_{\text{tors}} \# \check{A}_{\text{tors}}(\mathbb{Q})} \text{Reg}(A/\mathbb{Q}),$$

where the definition of the many terms involved will be given at the speaker's discretion.
